

Clone-based Cloud Robotics System for Robot Teleoperation

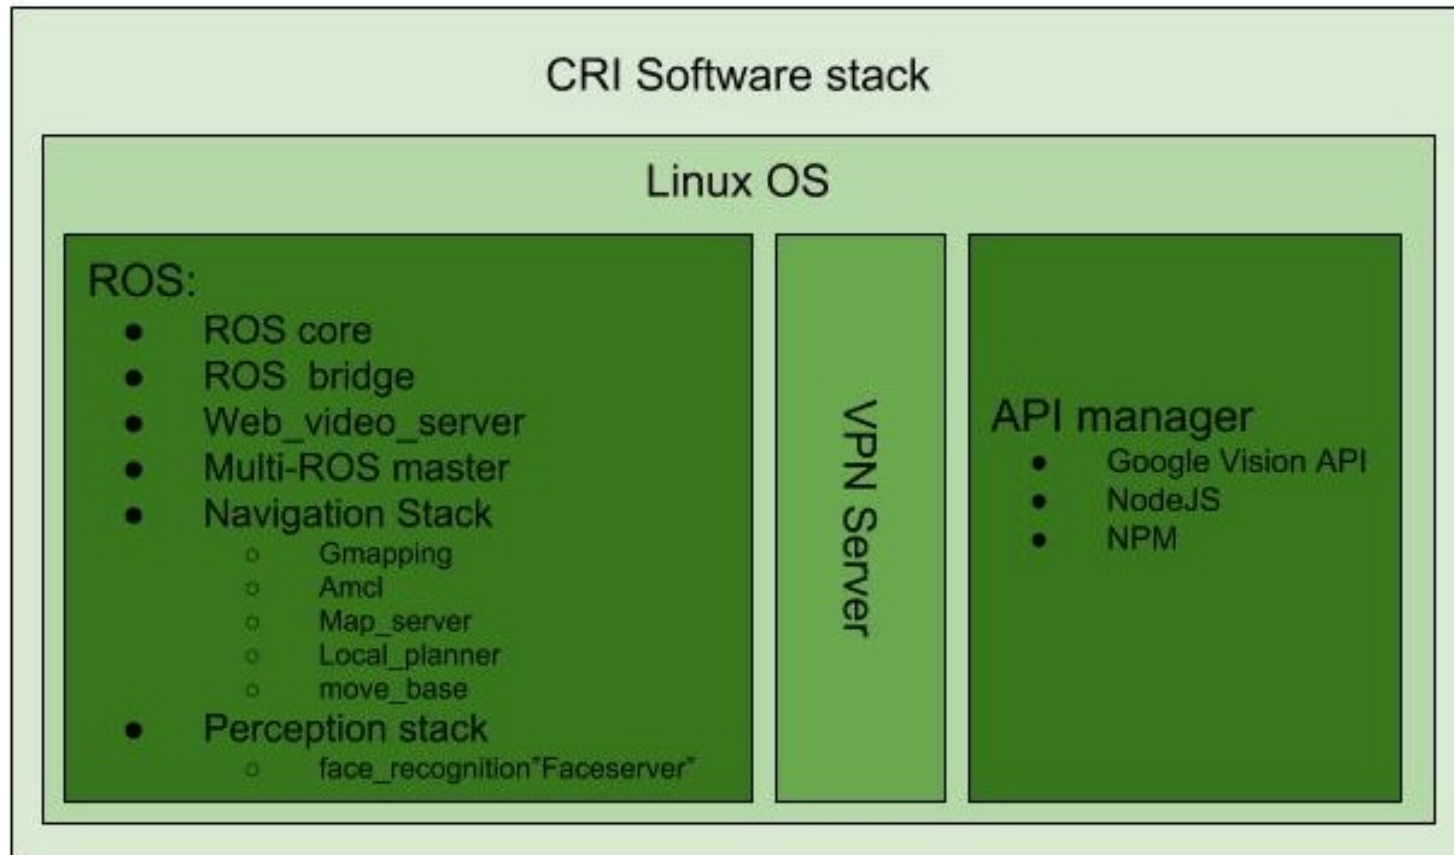

Hamza Aagela & Violeta Holmes

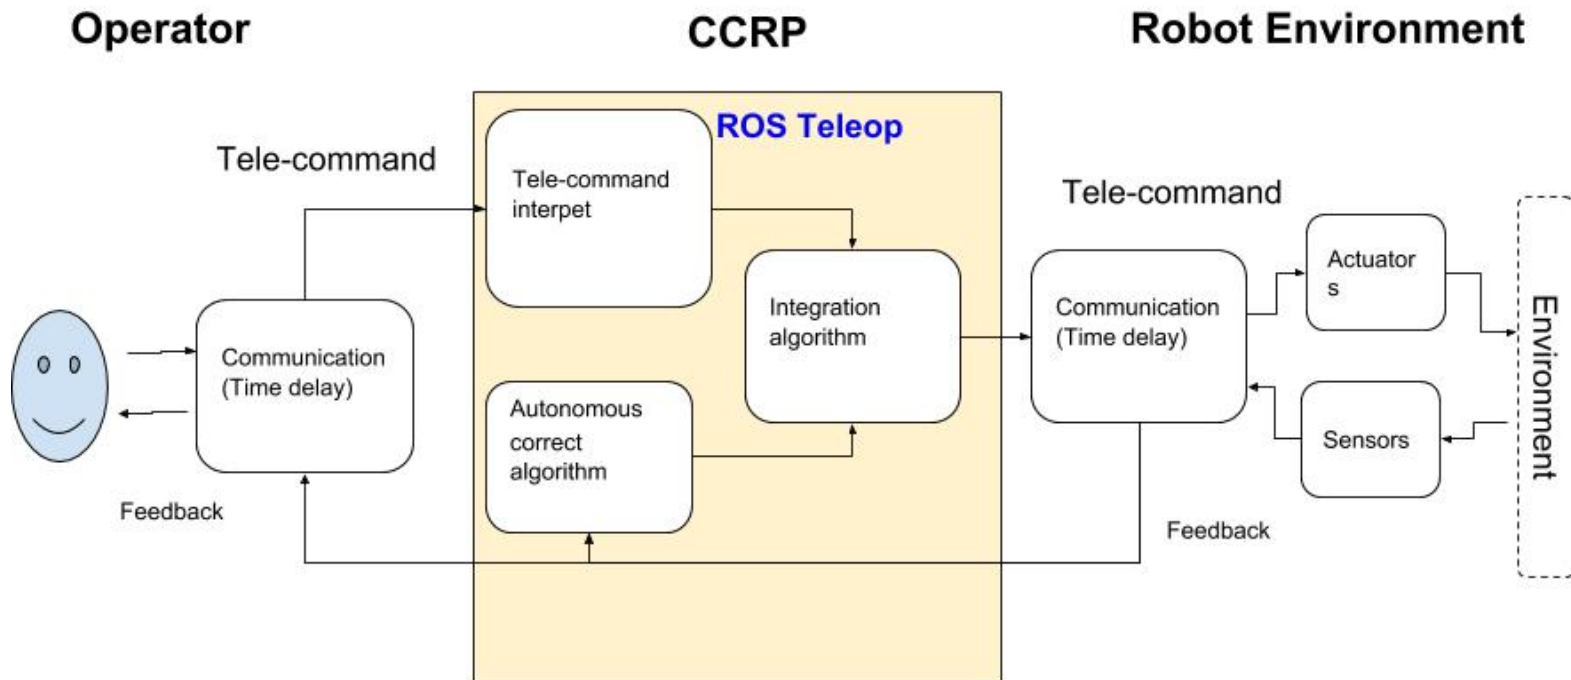

- ***Introduction***
- ***Aim***
- ***CCRP system architecture***
- ***Software stack***
- ***Teleoperation algorithm***
- ***Experiment requirements***
- ***Experiment setup***
- ***Experimental results***
- ***Summary***

- **Teleoperation was among the first applications in robotics back in the 1950s.**
- **Teleoperation is one way to combine robot skills and human operator abilities.**
- **The main challenges for the Teleoperation task in the cloud environment are security and communication constraints**
- **Robots are now able to assist humans in many demanding tasks.**
- **Teleoperation application:**
 - **Transportation**
 - **Underwater exploration**
 - **Telesurgery**
- **These applications require a highly reliable platform that can securely manage the communication between a robot and its operator**

- **Design and implement a cloud based teleoperation algorithm.**
- **Utilize clone based cloud robotic platform (CCRP) which is designed to provide platform-as-a-service (PaaS) for the client robots.**
- **Evaluate the capability of the CCRP system in handling real-time teleoperation for different types of robots.**

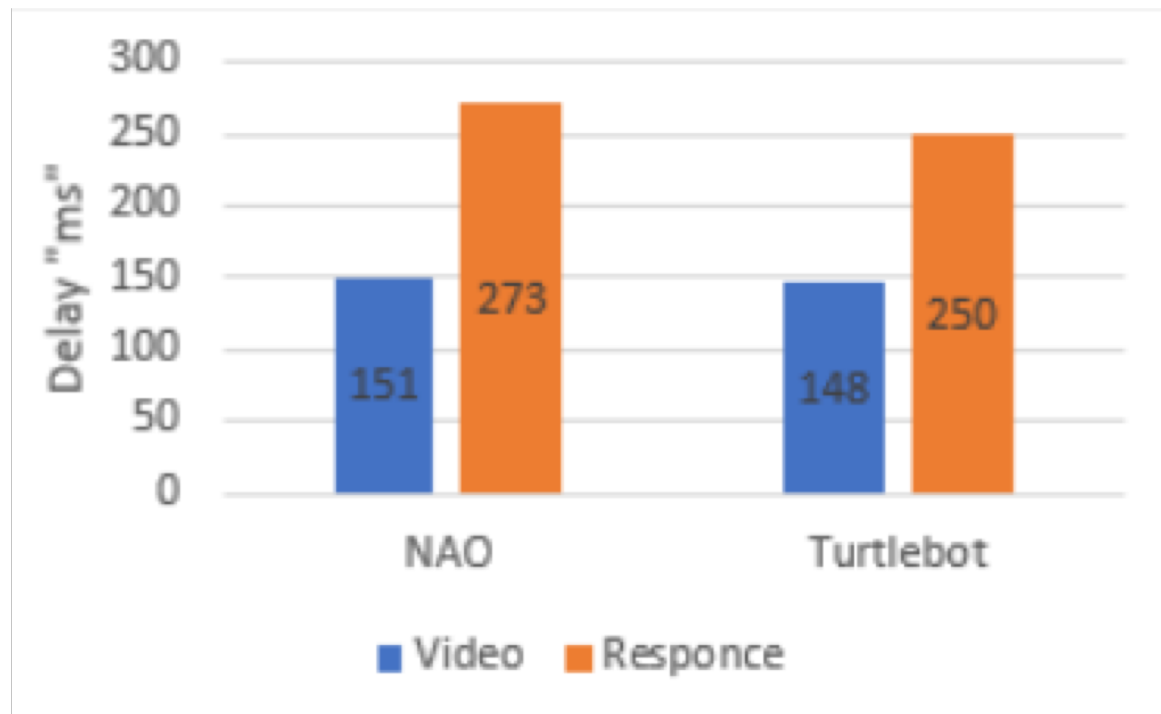

Fig. 1. A) Turtlebot robot B) NAO Humanoid robot

- Each robots are required to move from a point A to point B.
- Avoid one obstacle.

It took around 70s compared to the Turtlebot which takes only around 25s to accomplish the given task.

- **We presented a cloud-based robot teleoperation algorithm.**
- **The teleoperation is an effective approach in combining a robot skills and a human operator abilities.**
- **The result of our experiments show that the CCRP is capable of supporting manual teleoperation application (with an operator's control) due to a low robot response time.**
- **It can support heterogeneous robots within the multi-ROS environment.**
